

Package ‘sinkr’

September 1, 2015

Type Package

Title sinkr

Version 2.0

Date 2015-03-31

Author Marc Taylor <ningkiling@gmail.com>

Maintainer Marc Taylor <ningkiling@gmail.com>

Imports irlba, vegan

Description The sinkr package contains a collection of functions with some emphasis on multivariate methods and handling of geographic data fields.

addAlpha	<i>Add alpha channel (transparency) to colors</i>
----------	---

Description

Takes a vector of colors and adds an alpha channel at the given level of transparency.

Usage

```
addAlpha(COLORS, ALPHA)
```

Arguments

COLORS	Vector of any of the three kinds of R color specifications, i.e., either a color name (as listed by colors()), a hexadecimal string of the form "#rrggbb" or "#rrggbbaa" (see rgb), or a positive integer i meaning palette()[i].
ALPHA	A value (between 0 and 1) indicating the alpha channel (opacity) value.

Examples

```
# Make background image
x <- seq(-180, 180,, 30)
y <- seq(-90, 90,, 30)
grd <- expand.grid(x=x,y=y)
z <- sqrt(grd$x^2+grd$y^2)
dim(z) <- c(length(x), length(y))
pal <- colorRampPalette(c(rgb(1,1,1), rgb(0,0,0)))
COLORS <- pal(20)
image(x,y,z, col=COLORS)
```

```
# Add semi-transparent layer
z2 <- grd$x^2+grd$y
dim(z2) <- c(length(x), length(y))
pal <- colorRampPalette(c(rgb(0.5,1,0), rgb(0,1,1), rgb(1,1,1)))
COLORS <- addAlpha(pal(20), 0.4) # alpha chanel equals 0.4
image(x,y,z2, col=COLORS, add=TRUE)
```

bioEnv

Clarke and Ainsworth's BIO-ENV routine

Description

The bioEnv function performs Clarke and Ainsworth's (1993) "BIO-ENV" routine which compares (via a Mantel test) a fixed matrix of similarities to a variable one that test all possible variable combinations.

Usage

```
bioEnv(fix.mat, var.mat, fix.dist.method = "bray",
       var.dist.method = "euclidean", scale.fix = FALSE, scale.var = TRUE,
       output.best = 10, var.max = ncol(var.mat))
```

Arguments

fix.mat	The "fixed" matrix of community or environmental sample by variable values
var.mat	A "variable" matrix of community or environmental sample by variable values
fix.dist.method	The method of calculating dissimilarity indices bewteen samples in the fixed matrix (Uses the vegdist function from the vegan package to calculate distance matrices. See the documentation for available methods.). Defaults to Bray-Curtis dissimilarity "bray".
var.dist.method	The method of calculating dissimilarity indices bewteen samples in the variable matrix. Defaults to Euclidean dissimilarity "euclidean".
scale.fix	Logical. Should fixed matrix be centered and scaled (Defaults to FALSE, recommended for biologic data).
scale.var	Logical. Should fixed matrix be centered and scaled (Defaults to TRUE, recommended for environmental data to correct for differing units between variables).
output.best	Number of best combinations to return in the results object (Default=10).
var.max	Maximum number of variables to include. Defaults to all, var.max=ncol(var.mat).

Details

The R package "vegan" contains a version of Clarke and Ainsworth's (1993) BIOENV analysis ([bioenv](#)) which allows for the comparison of distance/similarity matrices between two sets of data having either samples or variables in common. The difference with bioEnv is that one has more flexibility with methods to apply to the fixed and variable multivariate matrices. The typical setup is in the exploration of environmental variables that best correlate to sample similarities of the biological community (e.g. species biomass or abundance), called "BIOENV". In this case, the

similarity matrix of the community is fixed, while subsets of the environmental variables are used in the calculation of the environmental similarity matrix. A correlation coefficient (typically Spearman rank correlation coefficient, "rho") is then calculated between the two matrices and the best subset of environmental variables can then be identified and further subjected to a permutation test to determine significance. The vegan package's `bioenv` function assumes BIOENV setup, and the similarity matrix of environmental data is assumed to be based on normalized "euclidean" distances. This makes sense with environmental data where one normalizes the data to remove the effect of differing units between parameters, yet in cases where the variable matrix is biological, one might want more flexibility (a Bray-Curtis measure of similarity is common given its non-parametric nature). For example, beyond the typical biological to environmental comparison (BIOENV setup), one can also use the routine to explore other types of relationships; e.g.:

ENVBIO: subset of biological variables that best correlate to the overall environmental pattern
 BIOBIO: subset of biological variables that best correlate to the overall biological pattern
 ENVENV: subset of environmental variables that best correlate to the overall environmental pattern

It is important to mention that one of the reasons why a variable biological similarity matrix is often less explored with the routine is that the number of possible subset combinations becomes computationally overwhelming when the number of species/groups is large - the total number of combinations being equal to $2^n - 1$, where n is the total number of variables. For this reason, Clarke and Warwick (1998) presented a stepwise routine (BVSTEP) (see [bvStep](#) for more efficient exploration of the subset combinations).

Examples

```
library(vegan)
data(varespec)
data(varechem)

res <- bioEnv(wisconsin(varespec), varechem,
              fix.dist.method="bray", var.dist.method="euclidean",
              scale.fix=FALSE, scale.var=TRUE
)
res
```

Description

The `bvStep` function performs Clarke and Ainsworth's (1993) "BVSTEP" routine which is a algorithm that searches for highest correlation (Mantel test) between dissimilarities of a fixed and variable multivariate datasets. The test is the same as that performed by the `bioEnv` function but the routine provides a more efficient search of combinations when the number of variables is large.

Usage

```
bvStep(fix.mat, var.mat, fix.dist.method = "bray",
       var.dist.method = "euclidean", scale.fix = FALSE, scale.var = TRUE,
       max.rho = 0.95, min.delta.rho = 0.001, random.selection = TRUE,
       prop.selected.var = 0.2, num.restarts = 10, var.always.include = NULL,
       var.exclude = NULL, output.best = 10)
```

Arguments

<code>fix.mat</code>	The "fixed" matrix of community or environmental sample by variable values
<code>var.mat</code>	A "variable" matrix of community or environmental sample by variable values
<code>fix.dist.method</code>	The method of calculating dissimilarity indices between samples in the fixed matrix (Uses the <code>vegdist</code> function from the <code>vegan</code> package to calculate distance matrices. See the documentation for available methods.). Defaults to Bray-Curtis dissimilarity "bray".
<code>var.dist.method</code>	The method of calculating dissimilarity indices between samples in the variable matrix. Defaults to Euclidean dissimilarity "euclidean".
<code>scale.fix</code>	Logical. Should fixed matrix be centered and scaled (Defaults to FALSE, recommended for biologic data).
<code>scale.var</code>	Logical. Should fixed matrix be centered and scaled (Defaults to TRUE, recommended for environmental data to correct for differing units between variables).
<code>max.rho</code>	Numeric value between 0 and 1. Provides a maximum Spearman rank correlation ("rho") by which to stop the searching process. This is especially important when conducting a "BIOBIO" or "ENVENV" type setup where rho will be equal to 1 with the full set of variables (see <code>bioEnv</code> for an explanation to these types of setups). Defaults to <code>max.rho=0.95</code>
<code>min.delta.rho</code>	Numeric value. Defines a minimum change in the improvement of Spearman rank correlation ("rho"). When not satisfied, <code>bvStep</code> will terminate the search process and return results of the best variable correlations.
<code>random.selection</code>	Logical. When <code>random.selection=TRUE</code> (Default), the algorithm will begin each restart with a random number of variables from the variable dataset. When <code>random.selection=FALSE</code> , a single search is conducted starting with all variables.
<code>prop.selected.var</code>	Numeric. Value between 0 and 1 indicating the proportion of variables to include at each restart.
<code>num.restarts</code>	Numeric. Number of restarts (Default: <code>num.restarts=50</code>)
<code>var.always.include</code>	Numeric vector. A vector of column numbers from the variable dataset to include at the each restart.

<code>var.exclude</code>	Numeric vector. A vector of column numbers from the variable dataset to always exclude at the each restart and during the search process.
<code>output.best</code>	Numeric value. Number of best combinations to return in the results object (Default=10).

Details

The variable multivariate data set has $2^n - 1$ possible combinations to test, where n is the number of variables. Testing all variable combinations is thus unrealistic, computationally, when the number of variables is high (e.g. 20 variables contain $>1e6$ combinations). This may often be the case when conducting a BIOBIO type analysis, where the number of species combinations to search can be quite large (see [bioEnv](#) for an explanation of other types of analyses beyond the typical "BIOENV"). Below is an example of a two-step search refinement for searching for subsets of variables that best correlate with a fixed multivariate set.

```

colorPalette

Color interpolation with uneven step size

Description

Color ramp with differing number of steps between color levels. Wrapper for [colorRamp](#).

Usage

```
colorPalette(steps, n.steps.between = NULL, ...)
```

Arguments

steps	colors to interpolate; must be a valid argument to <code>col2rgb()</code> .
n.steps.between	number of color steps in between each color. Allows one to stretch out specified colors more than others. Default is that all steps have the same weighting.
...	arguments to pass to colorRamp .

Details

This is a wrapper function for `colorRampPalette`. It allows for the definition of the number of intermediate colors between the main colors. Using this option one can stretch out colors that should predominate the palette spectrum. Additional arguments of `colorRampPalette` can also be added regarding the type and bias of the subsequent interpolation..

Examples

```
# Color scales with and without steps in between
op <- par(mfcol=c(2,1), omi=c(0.1,0.1,0.1,0.1), mai=c(1,0.2,0.2,0.2))
steps <- c("blue4", "cyan", "white", "yellow", "red4")
pal <- colorPalette(steps, space="rgb")
z=1:1000
imageScale(z, col=pal(41))
box()
steps <- c("blue4", "cyan", "white", "yellow", "red4")
pal <- colorPalette(steps, c(20,1,1,20), space="rgb")
z=1:1000
imageScale(z, col=pal(41))
box()
par(op)

# Use of transparency in palette (via alpha=TRUE)
op <- par(mar=c(0,0,0,0))
snow <- replace(volcano, volcano<150, NaN) * 1e-8*volcano^3
elevation.pal <- colorPalette(c("black", "blue", "red"), c(1,6))
snow.pal <- colorPalette(c(rgb(0.9,0.9,0.9,0), rgb(0.9,0.9,0.9,1)), alpha=TRUE)
image(volcano, col=elevation.pal(100), axes=FALSE)
image(snow, col=snow.pal(100), add=TRUE)
contour(volcano, add=TRUE, levels=150, col="white", lwd=2, cex=2)
text(0.3, 0.9, "Snow line", col="white")
par(op)
```

cov4gappy

Covariance matrix calculation for gappy data

Description

This function calculates a covariance matrix for data that contain missing values ('gappy data').

Usage

```
cov4gappy(F1, F2 = NULL)
```

Arguments

F1	A data field.
F2	An optional 2nd data field.

Details

This function gives comparable results to `cov(F1, y=F2, use="pairwise.complete.obs")` whereby each covariance value is divided by n number of shared values (as opposed to n-1 in the case of `cov()`). Furthermore, the function will return a 0 (zero) in cases where no shared values exist between columns; the advantage being that a covariance matrix will still be calculated in cases of very gappy data, or when spatial locations have accidentally been included without observations (i.e. land in fields of aquatic-related parameters).

Value

A matrix with covariances between columns of F1. If both F1 and F2 are provided, then the covariances between columns of F1 and the columns of F2 are returned.

Examples

```
# Create synthetic data
set.seed(1)
mat <- matrix(rnorm(500, sd=10), nrow=50, ncol=10)
matg <- mat
matg[sample(length(mat), 0.5*length(mat))] <- NaN # Makes 50% missing values
matg # gappy matrix

# Calculate covariance matrix and compare to 'cov' function output
c1 <- cov4gappy(matg)
c2 <- cov(matg, use="pairwise.complete.obs")
plot(c1,c2, main="covariance comparison", xlab="cov4gappy", ylab="cov")
abline(0,1,col=8)
```

dineof

*DINEOF (Data Interpolating Empirical Orthogonal Functions)***Description**

This function is based on the DINEOF (Data Interpolating Empirical Orthogonal Functions) procedure described by Beckers and Rixon (2003). The procedure has been shown to accurately determine Empirical Orthogonal Functions (EOFs) from gappy data sets (Taylor et al. 2013). Rather than directly return the EOFs, the results of the dineof function is a fully interpolated matrix which can then be subjected to a final EOF decomposition with eof, prcomp, or other EOF/PCA function of preference.

Usage

```
dineof(Xo, n.max = NULL, ref.pos = NULL, delta.rms = 1e-05)
```

Arguments

Xo	A gappy data field.
n.max	A maximum number of EOFs to iterate (leave equalling "NULL" if algorithm should proceed until convergence)
ref.pos	A vector of non-gap reference positions by which errors will be assessed via root mean squared error ("RMS"). If ref.pos = NULL, then either 30 or 1% of the non-gap values (which ever is larger) will be sampled at random.
delta.rms	The threshold for RMS convergence.

Value

Results of `dineof` are returned as a list containing the following components:

<code>Xa</code>	The data field with interpolated values (via EOF reconstruction) included.
<code>n.eof</code>	The number of EOFs used in the final solution.
<code>RMS</code>	A vector of the RMS values from the iteration.
<code>NEOF</code>	A vector of the number of EOFs used at each iteration.

```

earthBear

Directional bearing between two geographic locations

Description

earthBear calculates bearing (in degrees) between two lon/lat positions. One of the lon/lat positions (i.e. lon1 and lat1) can be a vector of positions to compare against the other lon/lat position (i.e. lon2 and lat2)

Usage

```
earthBear(lon1, lat1, lon2, lat2)
```

Arguments

lon1	longitude 1 (in decimal degrees)
lat1	Latitude 1 (in decimal degrees)
lon2	longitude 2 (in decimal degrees)
lat2	Latitude 2 (in decimal degrees)

Value

Vector of directional bearings (degrees)

Examples

```
earthBear(0,0,20,20)
```

earthDist

Earth distance between two geographic locations

Description

earthDist calculates distance (in kilometers) between two lon/lat positions. The function assumes a mean equatorial Earth radius of 6378.145 km. One of the lon/lat positions (i.e. lon1 and lat1) can be a vector of positions to compare against the other lon/lat position (i.e. lon2 and lat2)

Usage

```
earthDist(lon1, lat1, lon2, lat2)
```

Arguments

lon1	longitude 1 (in decimal degrees)
lat1	Latitude 1 (in decimal degrees)
lon2	longitude 2 (in decimal degrees)
lat2	Latitude 2 (in decimal degrees)

Value

Vector of distances (km)

Examples

```
earthDist(0,0,20,20)
```

eof

EOF (Empirical Orthogonal Functions analysis)

Description

This function conducts an Empirical Orthogonal Function analysis (EOF) via a covariance matrix (cov4gappy function) and is especially designed to handle gappy data (i.e. containing missing values - NaN)

Usage

```
eof(F1, centered = TRUE, scaled = FALSE, nu = NULL, method = NULL,
    recursive = FALSE)
```

Arguments

F1	A data field. The data should be arranged as samples in the column dimension (typically each column is a time series for a spatial location).
centered	Logical (TRUE/FALSE) to define if F1 should be centered prior to the analysis. Defaults to 'TRUE'
scaled	Logical (TRUE/FALSE) to define if F1 should be scaled prior to the analysis. Defaults to 'TRUE'
nu	Numeric value. Defines the number of EOFs to return. Defaults to return the full set of EOFs.
method	Method for matrix decomposition ('svd', 'eigen', 'irlba'). Defaults to 'svd' when method = NULL and 'irlba' when method = NULL and recursive = TRUE. Use of 'irlba' can dramatically speed up computation time when recursive = TRUE but may produce errors in computing trailing EOFs. Therefore, this option is only advisable when the field F1 is large and when only a partial decomposition is desired (i.e. $nu \ll \dim(F1)[2]$). All methods should give identical results when recursive=TRUE. svd and eigen give similar results for non-gappy fields, but will differ slightly with gappy fields due to decomposition of a nonpositive definite covariance matrix. Specifically, eigen will produce negative eigenvalues for trailing EOFs, while singular values derived from svd will be strictly positive.
recursive	Logical. When TRUE, the function follows the method of "Recursively Subtracted Empirical Orthogonal Functions" (RSEOF) (Taylor et al. 2013). RSEOF is a modification of a least squares EOF approach for gappy data (LSEOF) (see von Storch and Zwiers 1999)

Details

Taylor et al. (2013) demonstrated that the RSEOF approach more accurately estimates EOFs from a gappy field than the traditional LSEOF method. Pre-treatment of gappy fields through in EOF interpolation ([dineof](#)) may provide the most accurate EOFs, although computation time is substantially longer than RSEOF.

Value

Results of eof are returned as a list containing the following components:

u	EOFs.
Lambda	Singular values.
A	EOF coefficients (i.e. 'Principal Components').
tot.var	Total variance of field F1 (from cov4gappy).
F1_dim	Dimensions of field F1.
F1_center	Vector of center values from each column in field F1.
F1_scale	Vector of scale values from each column in field F1.

```

eofBoot

Calculate number of non-mixed EOFs (eof version)

Description

The eofBoot function uses a bootstrap randomization approach to calculate distributions of Empirical Orthogonal Function analysis (EOF) singular values with the [eof](#) function. EOF mode significance is assessed against the distributions of neighboring EOF singular values ("Lambda") calculated by the permuted models. A bootstrap routine follows the procedure of Babamoradi et al. (2013) whereby permutations sample rows (samples) more than once, which is a non-parametric approach does not make assumptions about the distribution of data.

Usage

```
eofBoot(F1, centered = TRUE, scaled = FALSE, nu = NULL, method = NULL,
        recursive = FALSE, nperm = 99)
```

Arguments

F1	A data field. The data should be arranged as samples in the column dimension (typically each column is a time series for a spatial location).
centered	Logical (TRUE/FALSE) to define if F1 should be centered prior to the analysis. Defaults to 'TRUE'
scaled	Logical (TRUE/FALSE) to define if F1 should be scaled prior to the analysis. Defaults to 'TRUE'
nu	Numeric value. Defines the number of EOFs to return. Defaults to return the full set of EOFs.
method	Method for matrix decomposition ('svd', 'eigen', 'irlba'). Defaults to 'svd' when method = NULL. Use of 'irlba' can dramatically speed up computation time when recursive = TRUE but may produce errors in computing trailing EOFs. Therefore, this option is only advisable when the field F1 is large and when only a partial decomposition is desired (i.e. $nu \ll \dim(F1)[2]$). All methods should give identical results when recursive=TRUE. svd and eigen give similar results for non-gappy fields, but will differ slightly with gappy fields due to decomposition of a nonpositive definite covariance matrix. Specifically, eigen will produce negative eigenvalues for trailing EOFs, while singular values derived from svd will be strictly positive.
recursive	Logical. When TRUE, the function follows the method of "Recursively Subtracted Empirical Orthogonal Functions" (RSEOF). See eof for details
nperm	Numeric. The number of null model permutations to calculate.

points(res$Lambda.orig)
abline(v=res$n.sig+0.5, lty=2, col=4)
mtext(paste("Non-mixed PCs =", res$n.sig), side=3, line=0.5, col=4)

```

eofNull

*Calculate significance of EOFs compared to a null model (eof version)***Description**

The eofNull function uses a randomization approach to calculate a null model for use in Empirical Orthogonal Function analysis (EOF) with the eof function. EOF mode significance is assessed against the distribution of EOF singular values ("Lambda") calculated by the null models

Usage

```

eofNull(F1, centered = TRUE, scaled = FALSE, nu = NULL, method = NULL,
        recursive = FALSE, nperm = 99)

```

Arguments

F1	A data field. The data should be arranged as samples in the column dimension (typically each column is a time series for a spatial location).
centered	Logical (TRUE/FALSE) to define if F1 should be centered prior to the analysis. Defaults to 'TRUE'
scaled	Logical (TRUE/FALSE) to define if F1 should be scaled prior to the analysis. Defaults to 'TRUE'
nu	Numeric value. Defines the number of EOFs to return. Defaults to return the full set of EOFs.
method	Method for matrix decomposition ('svd', 'eigen', 'irlba'). Defaults to 'svd' when method = NULL. Use of 'irlba' can dramatically speed up computation time when recursive = TRUE but may produce errors in computing trailing EOFs. Therefore, this option is only advisable when the field F1 is large and when only a partial decomposition is desired (i.e. nu << dim(F1)[2]). All methods should give identical results when recursive=TRUE. svd and eigen

give similar results for non-gappy fields, but will differ slightly with gappy fields due to decomposition of a nonpositive definite covariance matrix. Specifically, eigen will produce negative eigenvalues for trailing EOFs, while singular values derived from svd will be strictly positive.

recursive Logical. When TRUE, the function follows the method of "Recursively Subtracted Empirical Orthogonal Functions" (RSEOF). See [eof](#) for details

nperm Numeric. The number of null model permutations to calculate.

Examples

```
# Generate data
m=50
n=100
frac.gaps <- 0.5 # the fraction of data with NaNs
N.S.ratio <- 0.1 # the Noise to Signal ratio for adding noise to data
x <- (seq(m)*2*pi)/m
t <- (seq(n)*2*pi)/n

# True field
Xt <-
  outer(sin(x), sin(t)) +
  outer(sin(2.1*x), sin(2.1*t)) +
  outer(sin(3.1*x), sin(3.1*t)) +
  outer(tanh(x), cos(t)) +
  outer(tanh(2*x), cos(2.1*t)) +
  outer(tanh(4*x), cos(0.1*t)) +
  outer(tanh(2.4*x), cos(1.1*t)) +
  tanh(outer(x, t, FUN="+")) +
  tanh(outer(x, 2*t, FUN="+"))

Xt <- t(Xt)

# Noise field
set.seed(1)
RAND <- matrix(runif(length(Xt), min=-1, max=1), nrow=nrow(Xt), ncol=ncol(Xt))
R <- RAND * N.S.ratio * Xt

# True field + Noise field
Xp <- Xt + R

res <- eofNull(Xp, method="svd", centered=FALSE, scaled=FALSE, nperm=499)
ylim <- range(res$Lambda.orig, res$Lambda)
boxplot(res$Lambda, log="y", col=8, border=2, outpch="", ylim=ylim)
points(res$Lambda.orig)
abline(v=res$n.sig+0.5, lty=2, col=4)
mtext(paste("Significant PCs =", res$n.sig), side=3, line=0.5, col=4)
```

eofPred

EOF prediction

Description

The eofPred function predicts the principal component loadings of a new dataset with an eof object

Usage

```
eofPred(EOF, newdata = NULL, pcs = NULL)
```

Arguments

EOF	An object resulting from the function eof
newdata	new data to project onto eofs
pcs	The principal components (PCs) to use in the reconstruction (defaults to the full set of PCs: pcs=seq(ncol(EOF\$u)))

Value

A matrix of principal component loadings (as in EOF\$A)

Examples

```
### Non-gappy example
# Data
set.seed(1)
ptrain <- 0.5 # portion of data to use for training set
tmp <- sample(nrow(iris), nrow(iris)*ptrain)
train <- iris[tmp,1:4] # training set
valid <- iris[-tmp,1:4] # validation set

# EOF analysis
Efull <- eof(iris[,1:4]) # EOF of full data
Etrain <- eof(train) # EOF of training data

# Predict PCs of validation set
pred <- eofPred(Etrain, newdata=valid)
# plot against full data-derived PCs
plot(c(Efull$A[-tmp,]), c(pred))
abline(0,1, col=2)

# Predict PCs of full set
pred <- eofPred(Efull, newdata=iris[,1:4])
# plot against full data-derived PCs (should be equal)
plot(c(Efull$A), c(pred))
abline(0,1, col=2)

### gappy example
# Data
set.seed(1)
ptrain <- 0.5 # portion of data to use for training set
pgap <- 0.2 # portion of data that are gaps (e.g. NaNs)
irisg <- as.matrix(iris[,1:4])
irisg[sample(length(irisg), length(irisg)*pgap)] <- NaN
tmp <- sample(nrow(irisg), nrow(irisg)*ptrain)
traing <- irisg[tmp,] # training set
validg <- irisg[-tmp,] # validation set

# EOF analysis
Efullg <- eof(irisg, recursive=TRUE) # EOF of full data
Etraing <- eof(traing, recursive=TRUE) # EOF of training data
```

```

# Predict PCs of validation set
pred <- eofPred(Etrain, newdata=validg)
# plot against full data-derived PCs
plot(c(Efullg$A[-tmp,]), c(pred))
abline(0,1, col=3)
# Root mean squared error
rmse <- sqrt(mean((c(Efullg$A[-tmp,])-c(pred))^2, na.rm=TRUE))
rmse

# Predict PCs of full set
pred <- eofPred(Etrain, newdata=irisg)
plot(c(Efullg$A), c(pred))
rmse <- sqrt(mean((c(Efullg$A)-c(pred))^2, na.rm=TRUE))
rmse

```

eofRecon

*EOF reconstruction (Empirical Orthogonal Functions analysis)***Description**

This function reconstructs the original field from an EOF object of the function eof.

Usage

```
eofRecon(EOF, pcs = NULL)
```

Arguments

EOF	An object resulting from the function eof.
pcs	The principal components (PCs) to use in the reconstruction (defaults to the full set of PCs: pcs=seq(ncol(EOF\$u)))

Examples

```

set.seed(1)
iris.gappy <- as.matrix(iris[,1:4])
iris.gappy[sample(length(iris.gappy), 0.25*length(iris.gappy))] <- NaN
Er <- eof(iris.gappy, method="svd", recursive=TRUE) # recursive (RSEOF)
Enr <- eof(iris.gappy, method="svd", recursive=FALSE) # non-recursive (LSEOF)
iris.gappy.recon.r <- eofRecon(Er)
iris.gappy.recon.nr <- eofRecon(Enr)

# Reconstructed values vs. observed values
op <- par(mfrow=c(1,2))
lim <- range(iris.gappy, na.rm=TRUE)
plot(iris.gappy, iris.gappy.recon.r,
col=c(2:4)[iris$Species], main="recursive=TRUE", xlim=lim, ylim=lim)
abline(0, 1, col=1, lwd=2)
plot(iris.gappy, iris.gappy.recon.nr,
col=c(2:4)[iris$Species], main="recursive=FALSE", xlim=lim, ylim=lim)
abline(0, 1, col=1, lwd=2)
par(op)

```

```
# Reconstructed values from gappy data vs. all original values
op <- par(mfrow=c(1,2))
plot(as.matrix(iris[,1:4]), iris.gappy.recon.r,
col=c(2:4)[iris$Species], main="recursive=TRUE")
abline(0, 1, col=1, lwd=2)
plot(as.matrix(iris[,1:4]), iris.gappy.recon.nr,
col=c(2:4)[iris$Species], main="recursive=FALSE")
abline(0, 1, col=1, lwd=2)
```

expmat

Exponentiation of a matrix

Description

The expmat function performs can calculate the pseudoinverse (i.e. "Moore-Penrose pseudoinverse") of a matrix (EXP=-1) and other exponents of matrices, such as square roots (EXP=0.5) or square root of its inverse (EXP=-0.5). The function arguments are a matrix (MAT), an exponent (EXP), and a tolerance level for non-zero singular values. The function follows three steps: 1) Singular Value Decomposition (SVD) of the matrix; 2) Exponentiation of the singular values; 3) Re-calculation of the matrix with the new singular values

Usage

```
expmat(MAT, EXP, tol = NULL)
```

Arguments

MAT	A matrix.
EXP	An exponent to apply to the matrix MAT.
tol	Tolerance level for non-zero singular values.

Value

A matrix

Examples

```
# Example matrix from Wilks (2006)
A <- matrix(c(185.47,110.84,110.84,77.58),2,2)
A
solve(A) #inverse
expmat(A, -1) # pseudoinverse
expmat(expmat(A, -1), -1) #inverse of the inverse -return to original A matrix
expmat(A, 0.5) # square root of a matrix
expmat(A, -0.5) # square root of its inverse
expmat(expmat(A, -1), 0.5) # square root of its inverse (same as above)

# Pseudoinversion of a non-square matrix
set.seed(1)
D <- matrix(round(runif(24, min=1, max=100)), 4, 6)
D
expmat(D, -1)
expmat(t(D), -1)
```

```

# Pseudoinversion of a square matrix
set.seed(1)
D <- matrix(round(runif(25, min=1, max=100)), 5, 5)
solve(D)
expmat(D, -1)
solve(t(D))
expmat(t(D), -1)

### Examples from "corpcor" package manual
# a singular matrix
m = rbind(
  c(1,2),
  c(1,2)
)

# not possible to invert exactly
# solve(m) # produces an error
p <- expmat(m, -1)

# characteristics of the pseudoinverse
zapsmall( m %*% p %*% m ) == zapsmall( m )
zapsmall( p %*% m %*% p ) == zapsmall( p )
zapsmall( p %*% m ) == zapsmall( t(p %*% m ) )
zapsmall( m %*% p ) == zapsmall( t(m %*% p ) )

# example with an invertable matrix
m2 = rbind(
  c(1,1),
  c(1,0)
)
zapsmall( solve(m2) ) == zapsmall( expmat(m2,-1) )

```

fieldAnomaly

Calculate the daily or monthly anomaly of a field

Description

The fieldAnomaly function calculates an anomaly field by subtraction the daily or monthly means from each spatial location (columns) of a field.

Usage

```
fieldAnomaly(y, x, level = "daily")
```

Arguments

y	A matrix of the spatio-temporal field with rows being the temporal dimension and columns being the spatial dimension
x	A vector of the class "POSIXlt" containing the dates that correspond to the rows of matrix y.
level	Character string. Anomaly to compute ("daily" or "monthly")

Examples

```

set.seed(1)
Time <- seq.Date(as.Date("1990-01-01"), as.Date("1999-12-01"), by="month")
Space <- seq(0,pi,,30)
Signal <- sin(as.POSIXlt(Time)$mon/2)
Z <- outer(Signal, sin(Space))
Noise <- Z * 0.1 * array(rnorm(length(Z)), dim=dim(Z))
Z <- Z + Noise
Z.anom <- fieldAnomaly(y=Z, x=as.POSIXlt(Time), level="monthly")

zran <- c(-1,1) * max(abs(range(Z, Z.anom)))
pal <- colorRampPalette(c("blue", "cyan", "grey", "yellow", "red"))
op <- par(no.readonly=TRUE)
layout(matrix(c(1,2,3,3), nrow=2, ncol=2), widths=c(4,1), heights=c(2,2))
par(mar=c(5,5,3,1))
image(Time, Space, Z, col=pal(100), zlim=zran, main="Original")
image(Time, Space, Z.anom, col=pal(100), zlim=zran, main="Anomaly")
par(mar=c(5,0,3,5))
imageScale(Z, col=pal(100), zlim=zran, axis.pos=4)
mtext("Value", side=4, line=3)
par(op)

```

getcolors

*Select colors visually***Description**

The `getcolors` function allows one to select from a visual palette of 216 colors (i.e. color combinations from 6 levels of red, green, and blue).

Usage

```
getcolors(n)
```

Arguments

`n` Numeric value of the number of colors to select

Value

A vector of hexadecimal codings for colors (as in `rgb`).

Examples

```

# Make synthetic data
set.seed(1)
n <- 100
x <- seq(n)
y1 <- cumsum(rnorm(n))
y2 <- cumsum(rnorm(n))
y3 <- cumsum(rnorm(n))
y4 <- cumsum(rnorm(n))

```

```

ylim <- range(c(y1,y2,y3,y4))

# Select colors
COLS <- getcolors(4)

# Plot data with selected colors
plot(x, y1, ylim=ylim, t="l", col=COLS[1], lwd=3, ylab="")
lines(x, y2, col=COLS[2], lwd=3)
lines(x, y3, col=COLS[3], lwd=3)
lines(x, y4, col=COLS[4], lwd=3)
legend("topleft", legend=paste("y", 1:4, sep=""), col=COLS, lwd=3)

```

getcolors2

*Select colors visually***Description**

The `getcolors2` function allows one to select from a visual palette of 1200 colors (i.e. color combinations from 6 levels of red, green, and blue).

Usage

```
getcolors2(n)
```

Arguments

`n` Numeric value of the number of colors to select

Value

A vector of hexadecimal codings for colors (as in [rgb](#)).

Examples

```

# Make synthetic data
set.seed(1)
n <- 100
x <- seq(n)
y1 <- cumsum(rnorm(n))
y2 <- cumsum(rnorm(n))
y3 <- cumsum(rnorm(n))
y4 <- cumsum(rnorm(n))
ylim <- range(c(y1,y2,y3,y4))

# Select colors
COLS <- getcolors2(4)

# Plot data with selected colors
plot(x, y1, ylim=ylim, t="l", col=COLS[1], lwd=3, ylab="")
lines(x, y2, col=COLS[2], lwd=3)
lines(x, y3, col=COLS[3], lwd=3)
lines(x, y4, col=COLS[4], lwd=3)

```

```
legend("topleft", legend=paste("y", 1:4, sep=""), col=COLS, lwd=3)
```

gmtColors

GMT palette colors

Description

gmtColors provides colors used in various palettes used by Generic Mapping Tools (**GMT**)

Usage

```
gmtColors(pal.name = "relief")
```

Arguments

pal.name	A palette name - One of the following 19 palette names: ("cool", "copper", "gebco", "globe", "gray", "haxby", "hot", "jet", "no_green", "ocean", "polar", "rainbow", "red2green", "relief", "sealand", "seis", "split", "topo", "wysiwyg")
----------	--

Value

a vector of hexadecimal color levels of the desired palette

Examples

```
# Visualization of palettes derived from GMT colors
pnames <- c(
  "cool", "copper", "gebco", "globe", "gray", "haxby",
  "hot", "jet", "no_green", "ocean", "polar", "rainbow",
  "red2green", "relief", "sealand", "seis", "split", "topo", "wysiwyg"
)
txtCol <- c(rep(1,16), "white", rep(1,3))

op <- par(mar=c(0.1,0.1,0.1,0.1), mfrow=c(length(pnames), 1))
for(i in seq(pnames)){
  pal <- colorRampPalette(gmtColors(pal.name=pnames[i]))
  image(matrix(seq(20), nrow=20, ncol=1), col=pal(20), axes=FALSE)
  box()
  usr <- par()$usr
  text(mean(usr[1:2]), mean(usr[3:4]), labels=pnames[i],
       font=2, cex=1, col=txtCol[i])
}
par(op)

# Application to \code{image} plot
relief.pal <- colorRampPalette(gmtColors("relief"))
op <- par(mar=c(1,1,1,1))
image(volcano, col=relief.pal(100), axes=FALSE)
par(op)
```

imageScale

*Make a color scale to accompany an image or other plot***Description**

The imageScale function is wrapper for imageScale and accepts the same arguments. It converts a vector of values (z) to a vector of color levels. One must define the number of colors. The limits of the color scale ("zlim") or the break points for the color changes("breaks") can also be defined. When breaks and zlim are defined, breaks overrides zlim. All arguments are similar to those in the image function. Appearance is best when incorporated with [layout](#).

Usage

```
imageScale(z, zlim, col = heat.colors(12), breaks, axis.pos = 1,
  add.axis = TRUE, xlim = NULL, ylim = NULL, ...)
```

Arguments

z	A vector or matrix of values.
zlim	Limits of the color scale values.
col	Vector of color values (default is 12 colors from the heat.colors palette).
breaks	Break points for color changes. If breaks is specified then zlim is unused and the algorithm used follows cut , so intervals are closed on the right and open on the left except for the lowest interval which is closed at both ends.
axis.pos	Position of the axis (1=bottom, 2=left, 3=top, 4=right) (default = 1).
add.axis	Logical (TRUE/FALSE). Defines whether the axis is added (default: TRUE).
xlim	Limits for the x-axis.
ylim	Limits for the y-axis.
...	Additional graphical parameters to pass to the image function.

Examples

```
# Make color palettes
pal.1=colorRampPalette(c("green4", "orange", "red", "white"), space="rgb", bias=0.5)
pal.2=colorRampPalette(c("blue", "cyan", "yellow", "red", "pink"), space="rgb")

# Make images with corresponding scales
op <- par(no.readonly = TRUE)
layout(matrix(c(1,2,3,0,4,0), nrow=2, ncol=3), widths=c(4,4,1), heights=c(4,1))
#layout.show(4)
#1st image
breaks <- seq(min(volcano), max(volcano),length.out=100)
par(mar=c(1,1,1,1))
image(seq(dim(volcano)[1]), seq(dim(volcano)[2]), volcano,
col=pal.1(length(breaks)-1), breaks=breaks-1e-8, xaxt="n", yaxt="n", ylab="", xlab="")
#Add additional graphics
levs <- pretty(range(volcano), 5)
contour(seq(dim(volcano)[1]), seq(dim(volcano)[2]), volcano, levels=levs, add=TRUE)
#Add scale
par(mar=c(3,1,1,1))
```

```

imageScale(volcano, col=pal.1(length(breaks)-1), breaks=breaks-1e-8,axis.pos=1)
abline(v=levs)
box()

#2nd image
breaks <- c(0,100, 150, 170, 190, 200)
par(mar=c(1,1,1,1))
image(seq(dim(volcano)[1]), seq(dim(volcano)[2]), volcano,
col=pal.2(length(breaks)-1), breaks=breaks-1e-8, xaxt="n", yaxt="n", ylab="", xlab="")
#Add additional graphics
levs=breaks
contour(seq(dim(volcano)[1]), seq(dim(volcano)[2]), volcano, levels=levs, add=TRUE)
#Add scale
par(mar=c(1,1,1,3))
imageScale(volcano, col=pal.2(length(breaks)-1), breaks=breaks-1e-8,
axis.pos=4, add.axis=FALSE)
axis(4,at=breaks, las=2)
box()
abline(h=levs)
par(op)

```

jetPal

*jet palette***Description**

jetPal is a palette of colors similar that found in Matlab. This is a nice general palette for data exploration - similar to a rainbow palette but does not cycle back to the lower color level (dark blue -> cyan -> yellow -> dark red).

Usage

```
jetPal(n)
```

Arguments

n Number of colors to generate

Examples

```
image(volcano, col=jetPal(50))
```

lonLatFilter

*Filter lon/lat positions that fall within defined boundaries***Description**

lonLatFilter Tests whether lon/lat positions fall within a defined box of lon/lat borders (location on border returns TRUE)

Usage

```
lonLatFilter(lon_vector, lat_vector, west, east, south, north)
```

Arguments

lon_vector	Longitude 1 (in decimal degrees)
lat_vector	Latitude 1 (in decimal degrees)
west	West longitude border (decimal degrees)
east	East longitude border (decimal degrees)
south	South latitude border (decimal degrees)
north	North latitude border (decimal degrees)

Value

Vector of position inclusion in the defined lon/lat borders

Examples

```
set.seed(1)
n <- 1000
Pos <- list(lon=runif(n, min=-180, max=180), lat=runif(n, min=-180, max=180))
# Check to see if positions are within boundaries
res <- lonLatFilter(Pos$lon, Pos$lat, -20, 20, -40, 40)
# Plot
op <- par(mar=c(4,4,1,1))
plot(Pos$lon, Pos$lat, pch=21, col=1, bg=2*res)
rect(-20, -40, 20, 40, border=3)
par(op)
```

Isos

List top n objects by size

Description

The function `lsos` lists the top `n` objects in memory.

Usage

```
lsos(pos = 1, pattern, order.by = "Size", decreasing = TRUE,
     head = TRUE, n = 10)
```

Arguments

pos	where to look for the object (see get , 'Details'); if omitted search as if the name of the object appeared unquoted in an expression.
pattern	an optional regular expression (see ls). Only names matching pattern are returned. see glob2rx can be used to convert wildcard patterns to regular expressions.
order.by	Order list by one of the following: "Type", "Size", "Rows", "Columns"
decreasing	Logical. Decreasing in size (i.e. largest objects at top of list.) (Default=TRUE)

head	Logical (Default=TRUE). Should only the head be returned in the results of a <code>data.frame</code> . Argument <code>n</code> defines how many objects to include.
n	Numeric value (Default=10). Defines how many objects to include in results

Value

a `data.frame` object

References

<http://stackoverflow.com/questions/1358003/tricks-to-manage-the-available-memory-in-an-r-session>

Examples

```
x1 <- matrix(rnorm(10000), 100, 100)
x2 <- as.data.frame(matrix(rnorm(1000), 100, 10))
x3 <- rnorm(1000)
lsos()
rm(list=c("x1", "x2", "x3"))
```

matrixPoly

Make polygons from a matrix

Description

`matrixPoly` creates a list of polygon coordinates given a matrix `z` and corresponding `x` and `y` coordinates for the dimensions of `z`.

Usage

```
matrixPoly(x, y, z, n = NULL)
```

Arguments

<code>x,y</code>	Optional vectors of values for matrix <code>z</code> rows (<code>x</code>) and columns (<code>y</code>). If excluded, the function assumes the values to be a evenly-spaced sequence from 0 to 1.
<code>z</code>	A matrix
<code>n</code>	An optional vector of element positions of <code>z</code> for polygon creation

Value

List of polygon coordinates for each element of `z`

Examples

```
# Make sythetic data
set.seed(1)
m=8
n=10
x <- seq(m)
y <- seq(n)
z <- matrix(runif(m*n), nrow=m, ncol=n)
```

```

# Ex 1 - add another image layer
image(x, y, z, col=grey.colors(20))
N <- sample(1:(m*n),20)
z2 <- NaN*z
z2[N] <- 1
image(x, y, z2, col=rgb(0,0,1,0.4), add=TRUE)
box()

# Ex 2 - add polygons
image(x, y, z, col=grey.colors(20))
poly <- matrixPoly(x, y, z=z, n=N)
sapply(poly, function(X){polygon(X, col=rgb(1,1,0,0.4), border=1)})
box()

# Ex 3 - add polygons to unequal grid
x2 <- cumsum(round(runif(m, min=1, max=10)))
y2 <- cumsum(round(runif(n, min=1, max=10)))
image(x2, y2, z, col=grey.colors(20))
poly <- matrixPoly(x2, y2, z=z, n=N)
sapply(poly, function(X){polygon(X, col=rgb(1,0,0,0.4), border=1)})
box()

```

nearest	<i>Calculate the nearest element in a vector as compared to a reference value</i>
---------	---

Description

the nearest function returns the position of a vector that is closest to a defined value by determining the element with the smallest squared distance.

Usage

```
nearest(value, lookup_vector)
```

Arguments

value	A numeric reference value
lookup_vector	The vector to compare to the reference value

Value

Vector element index of nearest value

Examples

```

set.seed(1)
x <- runif(10, min=0, max=100)
res <- nearest(50, x)
plot(x)
abline(h=50, col=8, lty=2)
points(res, x[res], pch=20, col=2)

```

newLonLat	<i>Directional bearing between two geographic locations</i>
-----------	---

Description

newLonLat calculates a new lon/lat position given an starting lon/lat position, a bearing and a distance to the new lon/lat position. Either the lon and lat arguments or the bearing and distance arguments can be a vector, whereby a vector of new locations will be calculated.

Usage

```
newLonLat(lon, lat, bearing, distance)
```

Arguments

lon	Longitude 1 (in decimal degrees)
lat	Latitude 1 (in decimal degrees)
bearing	Longitude 2 (in decimal degrees)
distance	Distance to new lon/lat position (km)

Value

List of new lon/lat locations

Examples

```
# Single new lon/lat position calculation
newLonLat(0,0,45,1000)

# Vector of new lon/lat positions and plot
startPos <- list(lon=0,lat=0)
endPos <- newLonLat(startPos$lon, startPos$lat, seq(0,360,20), 1000)
plot(1, t="n", xlim=range(endPos$lon), ylim=range(endPos$lat), xlab="lon", ylab="lat")
segments(startPos$lon, startPos$lat, endPos$lon, endPos$lat, col=rainbow(length(endPos$lon)))
points(startPos$lon, startPos$lat)
points(endPos$lon, endPos$lat)
```

newRange	<i>Define a new range for a numeric</i>
----------	---

Description

The newRange function scales a numeric vector to a new range as defined by minimum and maximum extreme values.

Usage

```
newRange(x, new.min = 0, new.max = 1)
```

Arguments

x	a numeric vector
new.min	numeric value of new minimum range value
new.max	numeric value of new maximum range value

Examples

```

y <- runif(100, min=0, max=2)
y2 <- newRange(y, new.min=0, new.max=1)
plot(y, t="1")
lines(y2, col=2)

plot(y, y2)

```

northTest

*North's Rule of Thumb for EOF significance***Description**

The northTest function assesses the uniqueness of EOF modes through assumptions of error on singular values ("Lambda") as described by North et al (1982). Overlapping error limits between neighboring Lambda values indicates a possible mixture of signals. A similar test via bootstrapping method can be done with the [prcompBoot](#) or [eofBoot](#) functions.

Usage

```
northTest(x, Lambda)
```

Arguments

x	Matrix. Field used during EOF decomposition
Lambda	Vector of singular values representing variance magnitudes explained by each EOF mode. Results of prcomp will need to be squared from their standard deviation values (e.g. Lambda=res\$sdev^2).

```

plotStacked

Stacked plot

Description

plotStacked makes a stacked plot where each y series is plotted on top of each other using filled polygons.

Usage

```

plotStacked(x, y, order.method = "as.is", ylab = "", xlab = "",
  border = NULL, lwd = 1, col = rainbow(length(y[1, ])), ylim = NULL,
  ...)

```

Arguments

x	A vector of values
y	A matrix of data series (columns) corresponding to x
order.method	Method of ordering y plotting order. One of the following: c("as.is", "max", "first"). "as.is" - plot in order of y column. "max" - plot in order of when each y series reaches maximum value. "first" - plot in order of when each y series first value > 0.
ylab	y-axis labels
xlab	x-axis labels
border	Border colors for polygons corresponding to y columns (will recycle) (see ?polygon for details)
lwd	Border line width for polygons corresponding to y columns (will recycle)
col	Fill colors for polygons corresponding to y columns (will recycle).
ylim	y-axis limits. If ylim=NULL, defaults to c(0, 1.2*max(apply(y,1,sum)).
...	Other plot arguments

Examples

```
#Create data
set.seed(1)
m <- 500
n <- 30
x <- seq(m)
y <- matrix(0, nrow=m, ncol=n)
colnames(y) <- seq(n)
for(i in seq(ncol(y))){
  mu <- runif(1, min=0.25*m, max=0.75*m)
  SD <- runif(1, min=5, max=20)
  TMP <- rnorm(1000, mean=mu, sd=SD)
  HIST <- hist(TMP, breaks=c(0,x), plot=FALSE)
  fit <- smooth.spline(HIST$counts ~ HIST$mids)
  y[,i] <- fit$y
}
y <- replace(y, y<0.01, 0)

#Ex.1 : Color by max value)
pal <- colorRampPalette(c(rgb(0.85,0.85,1), rgb(0.2,0.2,0.7)))
BREAKS <- pretty(apply(y,2,max),8)
LEVS <- levels(cut(1, breaks=BREAKS))
COLS <- pal(length(BREAKS)-1)
z <- val2col(apply(y,2,max), col=COLS)

#Create stacked plot (plot order = "as.is")
plotStacked(x,y, xlim=c(100, 400), ylim=c(0, 1.2*max(apply(y,1,sum), na.rm=TRUE)),
  yaxs="i", col=z, border="white", lwd=0.5)

#Create stacked plot (plot order = "max")
plotStacked(x,y, xlim=c(100, 400), ylim=c(0, 1.2*max(apply(y,1,sum), na.rm=TRUE)),
  order.method="max", yaxs="i", col=z, border="white", lwd=0.5)

#Ex. 2 : Color by first value
ord <- order(apply(y, 2, function(r) min(which(r>0)))))
```

```

y2 <- y[, ord]
pal <- colorRampPalette(c("blue", "cyan", "yellow", "red"))
z <- pal(ncol(y2))

#Create stacked plot (plot order = "as.is")
plotStacked(x,y2, xlim=c(100, 400), ylim=c(0, 1.2*max(apply(y2,1,sum), na.rm=TRUE)),
yaxs="i", col=z, border=1, lwd=0.25)

#Create stacked plot (plot order = "max")
plotStacked(x,y2, xlim=c(100, 400), ylim=c(0, 1.2*max(apply(y2,1,sum), na.rm=TRUE)),
order.method="max", yaxs="i", col=z, border=1, lwd=0.25)

```

plotStream

Stream plot

Description

plotStream makes a "stream plot" where each y series is plotted as stacked filled polygons on alternating sides of a baseline. A random wiggle is applied through the arguments `frac.rand` and `spar` such that each plot will be different unless preceded by a random seed (e.g. `set.seed(1)`).

Usage

```

plotStream(x, y, order.method = "as.is", frac.rand = 0.1, spar = 0.2,
  center = TRUE, ylab = "", xlab = "", border = NULL, lwd = 1,
  col = rainbow(length(y[, 1])), ylim = NULL, ...)

```

Arguments

<code>x</code>	A vector of values
<code>y</code>	A matrix of data series (columns) corresponding to <code>x</code>
<code>order.method</code>	Method of ordering y plotting order. One of the following: <code>c("as.is", "max", "first")</code> . <code>"as.is"</code> - plot in order of y column. <code>"max"</code> - plot in order of when each y series reaches maximum value. <code>"first"</code> - plot in order of when each y series first value > 0.
<code>frac.rand</code>	Fraction of the overall data "stream" range used to define the range of random wiggle (uniform distribution) to be added to the baseline <code>g0</code>
<code>spar</code>	Setting for <code>smooth.spline</code> function to make a smoothed version of baseline <code>"g0"</code>
<code>center</code>	Logical. If TRUE, the stacked polygons will be centered so that the middle, i.e. baseline (<code>g0</code>), of the stream is approximately equal to zero. Centering is done before the addition of random wiggle to the baseline.
<code>ylab</code>	y-axis labels
<code>xlab</code>	x-axis labels
<code>border</code>	Border colors for polygons corresponding to y columns (will recycle) (see <code>?polygon</code> for details)
<code>lwd</code>	Border line width for polygons corresponding to y columns (will recycle)
<code>col</code>	Fill colors for polygons corresponding to y columns (will recycle).
<code>ylim</code>	y-axis limits. If <code>ylim=NULL</code> , defaults to <code>c(-0.7, 0.7)*max(apply(y, 1, sum))</code>
<code>...</code>	Other plot arguments

Value

A plot with stream visualization added

Examples

```
#Create data
set.seed(1)
m <- 500
n <- 30
x <- seq(m)
y <- matrix(0, nrow=m, ncol=n)
colnames(y) <- seq(n)
for(i in seq(ncol(y))){
  mu <- runif(1, min=0.25*m, max=0.75*m)
  SD <- runif(1, min=5, max=20)
  TMP <- rnorm(1000, mean=mu, sd=SD)
  HIST <- hist(TMP, breaks=c(0,x), plot=FALSE)
  fit <- smooth.spline(HIST$counts ~ HIST$mids)
  y[,i] <- fit$y
}
y <- replace(y, y<0.01, 0)

#Ex.1 : Color by max value)
pal <- colorRampPalette(c(rgb(0.85,0.85,1), rgb(0.2,0.2,0.7)))

LEVS <- levels(cut(1, breaks=BREAKS))
COLS <- pal(length(BREAKS)-1)
z <- val2col(apply(y,2,max), col=COLS)

#Plot order = "as.is"
plotStream(x,y, xlim=c(100, 400), center=TRUE, spar=0.3, frac.rand=0.2,
col=z, border="white", lwd=0.5)

#Plot order = "max"
plotStream(x,y, xlim=c(100, 400), center=TRUE, order.method="max", spar=0.3,
frac.rand=0.2, col=z, border="white", lwd=0.5)

#Ex. 2 : Color by first value
ord <- order(apply(y, 2, function(r) min(which(r>0))))
y2 <- y[, ord]
pal <- colorRampPalette(c("blue", "cyan", "yellow", "red"))
z <- pal(ncol(y2))

#Plot order = "as.is"
plotStream(x,y2, xlim=c(100, 400), center=FALSE, spar=0.1, frac.rand=0.05,
col=z, border=1, lwd=0.25)

#Plot order = "max"
plotStream(x,y2, xlim=c(100, 400), center=FALSE, order.method="max", spar=0.1,
frac.rand=0.05, col=z, border=1, lwd=0.25)

#Extremely wiggly, no borders, no box, no axes, black background
op <- par(bg=1, mar=c(0,0,0,0))
plotStream(x,y2, xlim=c(100, 400), center=FALSE, spar=0.3, frac.rand=1, col=z,
border=NA, axes=FALSE)
par(op)
```

prcompBoot

*Calculate number of non-mixed EOFs (prcomp version)***Description**

The prcompBoot function uses a bootstrap randomization approach to calculate distributions of Empirical Orthogonal Function analysis (EOF) singular values with the [prcomp](#) function. EOF mode significance is assessed against the distributions of neighboring EOF singular values ("Lambda") calculated by the permuted models. A bootstrap routine follows the procedure of Babamoradi et al. (2013) whereby permutations sample rows (samples) more than once, which is a non-parametric approach does not make assumptions about the distribution of data.

Usage

```
prcompBoot(x, retx = TRUE, center = TRUE, scale. = FALSE, tol = NULL,
           nperm = 99)
```

Arguments

`x, retx, center, scale., tol`
See [prcomp](#) for argument definitions.

`nperm` Numeric. The number of null model permutations to calculate.

References

Babamoradi, H., van den Berg, F., Rinnan, A, 2013. Bootstrap based confidence limits in principal component analysis - A case study, Chemometrics and Intelligent Laboratory Systems, Volume 120, pp. 97-105. doi:10.1016/j.chemolab.2012.10.007.

Examples

```
# Generate data
m=50
n=100
frac.gaps <- 0.5 # the fraction of data with NaNs
N.S.ratio <- 0.1 # the Noise to Signal ratio for adding noise to data
x <- (seq(m)*2*pi)/m
t <- (seq(n)*2*pi)/n

# True field

mtext(paste("Non-mixed PCs =", res$n.sig), side=3, line=0.5, col=4)

```

prcompNull	<i>Calculate significance of EOFs compared to a null model (prcomp version)</i>
------------	---

Description

The `prcompNull` function uses a randomization approach to calculate a null model for use in Empirical Orthogonal Function analysis (EOF) with the `prcomp` function. EOF mode significance is assessed against the distribution of EOF singular values ("Lambda") calculated by the null models

Usage

```
prcompNull(x, retx = TRUE, center = TRUE, scale. = FALSE, tol = NULL,
           nperm = 99)
```

Arguments

`x, retx, center, scale., tol`
See `prcomp` for argument definitions.

`nperm` Numeric. The number of null model permutations to calculate.

Examples

```

# Generate data
m=50
n=100
frac.gaps <- 0.5 # the fraction of data with NaNs
N.S.ratio <- 0.1 # the Noise to Signal ratio for adding noise to data
x <- (seq(m)*2*pi)/m
t <- (seq(n)*2*pi)/n

# True field
Xt <-
  outer(sin(x), sin(t)) +
  outer(sin(2.1*x), sin(2.1*t)) +
  outer(sin(3.1*x), sin(3.1*t)) +
  outer(tanh(x), cos(t)) +
  outer(tanh(2*x), cos(2.1*t)) +
  outer(tanh(4*x), cos(0.1*t)) +

```

```

outer(tanh(2.4*x), cos(1.1*t)) +
tanh(outer(x, t, FUN="+")) +
tanh(outer(x, 2*t, FUN="+"))

Xt <- t(Xt)

# Noise field
set.seed(1)
RAND <- matrix(runif(length(Xt), min=-1, max=1), nrow=nrow(Xt), ncol=ncol(Xt))
R <- RAND * N.S.ratio * Xt

# True field + Noise field
Xp <- Xt + R

res <- prcompNull(Xp, center=FALSE, scale=FALSE, nperm=499)
ylim <- range(res$Lambda.orig, res$Lambda)
boxplot(res$Lambda, log="y", col=8, border=2, outpch="", ylim=ylim)
points(res$Lambda.orig)
abline(v=res$n.sig+0.5, lty=2, col=4)
mtext(paste("Significant PCs =", res$n.sig), side=3, line=0.5, col=4)

```

prcompRecon

prcomp object reconstruction

Description

This function reconstructs the original field from an EOF object of the function [prcomp](#).

Usage

```
prcompRecon(pca, pcs = NULL)
```

Arguments

pca	An object resulting from the function prcomp .
pcs	The principal components ("PCs") to use in the reconstruction (defaults to the full set of PCs: <code>pcs=seq(pca\$sdev)</code>)

Examples

```

# prcomp
P <- prcomp(iris[,1:4])

# Full reconstruction
R <- prcompRecon(P)
plot(as.matrix(iris[,1:4]), R, xlab="original data", ylab="reconstructed data")
abline(0, 1, col=2)

# Partial reconstruction
RMSE <- NaN*seq(P$sdev)
for(i in seq(RMSE)){
  Ri <- prcompRecon(P, pcs=seq(i))
  RMSE[i] <- sqrt(mean((as.matrix(iris[,1:4]) - Ri)^2))
}

```

```
plot(RMSE, t="o", xlab="Number of pcs")
abline(h=0, lty=2)
```

ptlocator

Data point locator

Description

the ptlocator function allows for the selection of data points in an open graphical device via the [locator](#) function. Closest data points to the selected positions are determined via Euclidean distance following a scaling of x and y axes in order to give them equal weighting and remove the influence of differing units or ranges. Colored points are filled in for the data point that has the lowest distance to the clicked location, and the result gives the vector positions of the closest x, y data points.

Usage

```
ptlocator(n = 1, x, y, col = rgb(1, 0, 0, 0.5), pch = 20, ...)
```

Arguments

n	Number of points to select
x	Vector of x-axis values for the plotted data
y	Vector of y-axis values for the plotted data
col	Colors to use for plotting closest data points
pch	pch values to use for plotting closest data points
...	additional parameters for plotting closest data points

Value

A vector of point indices

Examples

```
set.seed(1)
n <- 200
x <- sort(runif(n, min=0, max=10*pi))
y <- sin(x) + rnorm(n, sd=0.2)

# Select 10 points at maxima and minima
plot(x, y)
pos <- ptlocator(10, x, y)
pos
```

reltext	<i>Add text using relative x,y plot coordinates</i>
---------	---

Description

reltext adds text using relative x,y plot coordinates. Wrapper for [text](#).

Usage

```
reltext(relx = 0.5, rely = 0.5, labels = seq_along(relx), ...)
```

Arguments

relx, rely numeric vectors of coordinates where the text labels should be written.

Examples

```
# Make data
set.seed(1)
n <- 100
a <- 3
b <- 5
x <- rnorm(n)
y <- a + b*x + rnorm(n, sd=2)
fit <- lm(y ~ x)

# Plot with regression results in top left corner
op <- par(mar=c(3,3,0.5,0.5), mgp=c(1.5,0.5,0), tcl=-0.25, las=1, bty="l")
plot(x, y)
abline(fit, lty=2, col=4)
reltext(0, 0.95, pos=4, col=4,
  labels=bquote( italic(y) == .(sprintf("%.2f", (coef(fit)[1])))+
    .(sprintf("%.2f", (coef(fit)[2]))~"*"~italic(x)
  )
)
reltext(0, 0.85, pos=4, col=4,
  labels=bquote( bolditalic(R)^2 == .(round(summary(fit)$adj.r.squared,2)) )
)
par(op)

# Plot multiple labels at once
plot(x, y)
abline(fit, lty=2, col=8)
reltext(c(0,0.95), c(0.95, 0.05), pos=c(4,3), col=c(3,4), labels=c("text1", "text2"))
```

round2reso	<i>Round to defined resolution increment</i>
------------	--

Description

round2res rounds a value to a given resolution (e.g. increments of 0.5) rather than the typical decimal place

Usage

```
round2reso(val, reso)
```

Arguments

val Vector. The values to be rounded

reso Numeric. The resolution or increment to use for rounding

Examples

```
set.seed(1)
n <- 10
x <- runif(n, min=0, max=20)
xr <- round2reso(x, 5) # rounded values to increments of 5
plot(x, t="n", ylim=c(0,20), pch=20)
abline(h=seq(0,20,5), col=8, lty=3)
points(x, col=1, pch=1)
points(xr, col=2, pch=20)
arrows(x0=seq(n), x1=seq(n), y0=x, y1=xr, length=0.1)
```

slp

Hadley SLP monthly mean dataset

Description

The slp data set contains monthly sea level pressure data for the Equatorial Pacific within the lat/lon range 180 W - 70 W and 30 S - 30 N, and spanning the years 1971-1998.

- **grid.** Dataframe of lon/lat coordinates corresponding to columns of slp\$field (5 deg resolution)
- **date.** Vector of monthly date values corresponding to rows of slp\$field
- **field.** Matrix of sea level pressure values by month and lon/lat position.

Usage

```
data(slp)
```

Format

A list consisting of: 1. a dataframe for lon/lat positions, 2. a vector of monthly date values, and 3. a matrix of slp values by month and lon/lat position (1536 rows, 231 columns)

Source

http://www.esrl.noaa.gov/psd/gcos_wgsp/Gridded/data.hadslp2.html

Examples

```
### Ex 1. Plot of single month
data(slp)
plot(slp$grid, col=val2col(slp$field[1000,]), pch=".", cex=30)

### Ex 2. EOF of slp

library(maps)

# Calculate monthly anomaly
slp.anom <- fieldAnomaly(slp$field, as.POSIXlt(slp$date), level="monthly")

# PCA
pca <- prcomp(slp.anom)

# Plot
neof <- 2 # EOF mode number to plot
op <- par(no.readonly=TRUE)
layout(matrix(c(1:2,3,3), nrow=2, ncol=2, byrow=TRUE), widths=c(4,1), heights=c(3,2))
layout.show(3)
# plot 1: map of PC loadings
par(mar=c(3,3,1,1))
zlim <- c(-1,1) * max(abs(pca$rotation[,neof]))
pal <- colorRampPalette(c(4,5,"grey90",7,2))
ncolor <- 25
plot(slp$grid, col=val2col(pca$rotation[,neof], zlim=zlim, col=pal(ncolor)),
     pch=".", cex=30, ylab="", xlab="")
map("world", add=TRUE)
# plot 2: color scale
par(mar=c(3,0,1,4))
imageScale(pca$rotation[,neof], axis.pos=4, zlim=zlim, col=pal(ncolor))
# plot 3: time series of PC
par(mar=c(3,3,1,1))
plot(slp$date, pca$x[,neof], t="l", ylab="", xlab="")
abline(h=0, col="grey", lty=2)
par(op)
```

spirographR

Make a spirograph-like design

Description

spirographR will produce spirograph-like design as either a hypotrochoid or an epitrochoid (depending on whether radius A or B is larger).

Usage

```
spirographR(x = 0, y = 0, a.rad = 1, b.rad = -4, bc = -2, rev = 4,
            n.per.rev = 360)
```

Arguments

<code>x,y</code>	Center coordinates of stationary circle 'a'
<code>a.rad</code>	Radius of stationary circle 'a'
<code>b.rad</code>	Radius of circle 'b' travelling around stationary circle 'a'
<code>bc</code>	Distance from the center of 'b' to a point 'c' which will turn with b as if attached to a stick.
<code>rev</code>	Number of revolutions that 'b' should travel around 'a'
<code>n.per.rev</code>	Number of radial increments to be calculated per revolution

Details

A positive value for 'b' will result in a epitrochoid, while a negative value will result in a hypotrochoid.

Examples

```
op <- par(mar=c(0,0,0,0), bg=1)
plot(spirographR(), t="l", col=6, lwd=3)
plot(spirographR(a.rad=1, b.rad=3.5, rev=7), t="l", col=7, lwd=3)
plot(spirographR(a.rad=4.1, b.rad=-6, rev=100, bc=2.3), t="l", col=5, lwd=1)
par(op)
```

sqbin	<i>Square binning of xy data</i>
-------	----------------------------------

Description

The sqbin function calculates frequencies in xy bins

Usage

```
sqbin(x, y, xint = NULL, yint = NULL, nxbin = 50, nybin = 50)
```

Arguments

<code>x</code>	a vector of x values
<code>y</code>	a vector of y values
<code>xint</code>	a vector of x intervals (end values). Defaults to values as specified by <code>pretty(x, n=nxbin)</code>
<code>yint</code>	a vector of y intervals (end values). Defaults to values as specified by <code>pretty(y, n=nybin)</code>
<code>nxbin</code>	number of x bins. Default=50. Not used when <code>xint</code> is defined.
<code>nybin</code>	number of y bins. Default=50. Not used when <code>yint</code> is defined.

Value

A matrix containing interval mid points (x,y), bin frequencies (z), and intervals (xint, yint).

Examples

```
# Synthetic data
set.seed(1)
n <- 1e6
x <- runif(n, min=-3, max=3)
y <- 4*x^2 + rnorm(n, sd=5)

sqbin.res <- sqbin(x,y)

# Plot
op <- par(mar=c(4,4,1,1))
image(sqbin.res, col=jetPal(20))
par(op)

# Plot with legend
op <- par(no.readonly = TRUE)
lo <- matrix(1:2, nrow=1, ncol=2)
layout(lo, widths=c(4,1), heights=c(4), respect=TRUE)
par(cex=1)
par(mar=c(3,3,1,1))
image(sqbin.res, col=jetPal(20))
par(mar=c(3,0,1,3))
imageScale(sqbin.res$z, col=jetPal(20), axis.pos=4)
par(op)
```

sst

Kaplan monthly mean anomaly dataset

Description

The sst data set contains monthly sea surface temperature anomaly data for the Equatorial Pacific within the lat/lon range 180 W - 70 W and 30 S - 30 N, and spanning the years 1956-2014.

- grid. Dataframe of lon/lat coordinates corresponding to columns of sst\$field (5 deg resolution)
- date. Vector of monthly date values corresponding to rows of sst\$field
- field. Matrix of sea level pressure values by month and lon/lat position.

Usage

```
data(sst)
```

Format

A list consisting of: 1. a dataframe for lon/lat positions, 2. a vector of monthly date values, and 3. a matrix of sst anomaly values by month and lon/lat position (1906 rows, 264 columns)

Source

http://www.esrl.noaa.gov/psd/data/gridded/data.kaplan_sst.html

Examples

```
### Ex 1. Plot of single month
data(sst)
plot(sst$grid, col=val2col(sst$field[1000,]), pch=".", cex=30)

### Ex 2. EOF of sst

library(maps)

# PCA
incl <- which(colSums(is.na(sst$field)) == 0) # remove columns corresponding to land
pca <- prcomp(sst$field[,incl])

# Plot
neof <- 1 # EOF mode number to plot

op <- par(no.readonly=TRUE)
layout(matrix(c(1:2,3,3), nrow=2, ncol=2, byrow=TRUE), widths=c(4,1), heights=c(3,2))
layout.show(3)
# plot 1: map of PC loadings
par(mar=c(3,3,1,1))
zlim <- c(-1,1) * max(abs(pca$rotation[,neof]))
pal <- colorRampPalette(c(4,5,"grey90",7,2))
ncolor <- 25
plot(sst$grid[incl,], col=val2col(pca$rotation[,neof], zlim=zlim, col=pal(ncolor)),
     pch=".", cex=30, ylab="", xlab="")
map("world", add=TRUE)
# plot 2: color scale
par(mar=c(3,0,1,4))
imageScale(pca$rotation[,neof], axis.pos=4, zlim=zlim, col=pal(ncolor))
# plot 3: time series of PC
par(mar=c(3,3,1,1))
plot(sst$date, pca$x[,neof], t="l", ylab="", xlab="")
abline(h=0, col="grey", lty=2)
par(op)
```

unscale

Unscale a matrix

Description

The `unscale` function unscales a numeric matrix that has been either centered or scaled by the [scale](#) function. This is done by reversing the first unscaling and then uncentering based on the object's attributes.

Usage

```
unscale(x, unscale = TRUE, uncenter = TRUE)
```

Arguments

x	a numeric matrix(like object) that has been centered and/or scaled by the scale function.
unscale	a logical value defining whether to unscale x.
uncenter	a logical value defining whether to uncenter x.

Examples

```
x <- matrix(1:16, 4, 4)
xcs <- scale(x, center=TRUE, scale=TRUE) # centered and scaled
xc <- scale(x, center=TRUE, scale=FALSE) # centered only
xs <- scale(x, center=FALSE, scale=TRUE) # scaled only

# compare difference to original
x - unscale(xcs)
x - unscale(xc)
x - unscale(xs)
```

val2col	<i>Convert values to color levels</i>
---------	---------------------------------------

Description

The `val2col` function converts a vector of values ("z") to a vector of color levels. One must define the number of colors. The limits of the color scale ("zlim") or the break points for the color changes("breaks") can also be defined. When breaks and zlim are defined, breaks overrides zlim. All arguments are similar to those in the `image` function.

Usage

```
val2col(z, zlim, col = heat.colors(12), breaks)
```

Arguments

z	A vector of values (default is 12 colors from the heat.colors palette).
zlim	Limits of the color scale values.
col	Vector of color values
breaks	Break points for color changes. If breaks is specified then zlim is unused and the algorithm used follows cut , so intervals are closed on the right and open on the left except for the lowest interval which is closed at both ends.

Examples

```
set.seed(1)
n <- 250
x <- seq(n)
y <- rnorm(n)

# Use all levels, evenly distributed breaks
Col <- val2col(y, col=rainbow(20))
plot(x,y, pch=21, bg=Col)
```

```
# Use limits, evenly distributed breaks
pal <- colorRampPalette(c("blue", "cyan", "yellow", "red"))
Col <- val2col(y, zlim=c(-1,1), col=pal(20))
plot(x,y, pch=21, bg=Col)
abline(h=c(-1,1), col=8, lty=2)

# Use custom breaks (break vector must have one more break than color)
Col <- val2col(y, col=topo.colors(6), breaks=c(-Inf, -2, -1, 0, 1, 2, Inf))
plot(x,y, pch=21, bg=Col)
abline(h=c(-Inf, -2, -1, 0, 1, 2, Inf), col=8, lty=2)
```
